【Abstract】 Objective The clinical, imaging and pathological manifestations of one patient at different stages of primary central nervous system lymphoma (PCNSL) have been analyzed to disclose its pathogenesis. **Methods and Results** A 29-year-old female patient showed recurrent onsets. On the first onset, the main clinical manifestation was blurred vision and visual field defect. Cranial MRI showed a patchy lesion in the right parietal and occipital lobes without obvious occupying sign. T₁WI showed slight low-intensity sign, T₂WI and FLAIR showed high-intensity signs. Enhanced scanning showed heterogeneous punctate enhancement. The lesion disappeared gradually after glucocorticoid impact therapy. Headache, vomiting and left limb paralysis were the main clinical manifestations on the second onset, and MRI showed a lesion in the right frontal and parietal lobes with obvious occupying sign and solid enhancement, low-intensity on T₁WI, high-intensity on T₂WI and FLAIR. The tumor was totally removed under microscope. Histological findings showed large tumor cells, rich cytoplasm, nuclei with various sizes and shapes, conspicuous mitosis, patchy necrosis, and interstitial small vessel hyperplasia. Immunohistochemical staining showed that membrane of tumor cells was positive for CD20, and nuclei were positive for paired box gene 5 (PAX5) and multiple myeloma oncogene 1 (MUM1). In a few tumor cells, membrane was

positive for CD10 and CD30, and nuclei were positive for cyclin D1. Besides, tumor cells were negative for CD3, anaplastic lymphoma kinase (ALK) and glial fibrillary acidic protein (GFAP). Ki-67 labeling index was about 80%. EBER in situ hybridization (ISH) assay showed that mRNA coded by Epstein-Barr (EB) virus was negative. The tumor showed angiotropic characteristics, and the walls of involved blood vessels were wrapped and destructed. The final diagnosis was confirmed as diffuse large B cell lymphoma.

Conclusions PCNSL has various imaging features, revealing as diffuse infiltrating or solid occupying lesions, which emerge as the result of its angiotropic characteristics.

类型淋巴瘤。原发性中枢神经系统淋巴瘤在国外好发于器官移植和免疫缺陷者,在我国多发生于免

疫功能正常者,高峰发病年龄为61~66岁,男性比例略高于女性,为1.1~1.7:1,中位生存期约为3个

月^[4-6]。获得性免疫缺陷综合征(AIDS)患者发生原发性中枢神经系统淋巴瘤与EB病毒(EBV)感染有关^[7]。在免疫功能正常者中,原发性中枢神经系统淋巴瘤与EB病毒感染无关。国外学者采用免疫组织化学染色将弥漫性大B细胞淋巴瘤区分为两种免疫类型,即生发中心B细胞型(GCB)和非生发中心B细胞型(non-GCB)^[8]。

原发性中枢神经系统淋巴瘤的临床表现通常无特异性,多表现为颅内高压和神经系统损害症状与体征。影像学表现多样,为实性占位性或浸润性病变,实性占位性病变MRI显示占位征象明显,T₁WI呈等或稍低信号,T₂WI呈稍低、等或高信号,单个或多个同质病变,边缘不规则,病变周围可见不同程度水肿,增强扫描病灶明显强化,表现为多种特殊的强化征象,如“缺口征”、“握拳征”、“脐凹征”和“蝴蝶征”等^[9-11],少数呈不均匀强化或未见明显强化;浸润性病变MRI信号改变与实性占位性病变相似,但占位征象不明显,强化征象亦不明显。该例患者发病早期病灶呈浸润性,再次发病时呈实性占位性,提示两种不同病灶可能是肿瘤不同发病阶段的表现。发病早期浸润性生长形成多发性卫星病灶,晚期卫星病灶融合为实体瘤。病变部位与原发性中枢神经系统淋巴瘤亚型相关^[12],生发中心B细胞型更常见于中心和中线附近,包括颅后窝,非生发中心B细胞型则主要位于侧脑室外白质区域。

原发性中枢神经系统淋巴瘤的影像学表现与其病理学特点密切相关。淋巴瘤细胞沿血管周围间隙[PVS,亦称Virchow-Robin间隙(VRS)]浸润形成“袖套”样结构,称为嗜血管特性^[2],是原发性中枢神经系统淋巴瘤的重要病理学特点。原发性中枢神经系统淋巴瘤的嗜血管特性与其发生与发展密切相关。(1)原发性中枢神经系统淋巴瘤源于血管周围间隙,与血管具有先天性密切关系:肿瘤发病机制一直存有争议。有学者认为,最初的淋巴瘤细胞由血管周围间隙内未分化的多能间叶细胞演变而来^[13-15]。主流观点认为,最初的淋巴瘤细胞是正常淋巴细胞受到致病因子诱导发生突变所致^[16]。中枢神经系统淋巴细胞是脑组织免疫监视的重要组成部分,血管周围间隙是中枢淋巴系统的主要组成部分^[17-18],是中枢神经系统免疫监视的主要通路,也是中枢神经系统淋巴细胞的主要聚集地。淋巴细胞穿过毛细血管后静脉内皮,进入血管周围间隙,通过脑膜淋巴管回到颈淋巴结。血管周围间隙

内的淋巴细胞在基因突变、病毒感染和(或)免疫功能异常等因素作用下发生恶性变,导致淋巴瘤。因此,无论何种学说均提示原发性中枢神经系统淋巴瘤源于血管周围间隙。(2)淋巴瘤细胞在血管周围间隙内形成后必然沿血管周围间隙向外浸润性生长,包绕血管形成“袖套”样结构,这也是大多数肿瘤的特性,易沿淋巴系统扩散。原发性中枢神经系统淋巴瘤沿血管周围间隙浸润性生长早期首先形成多发性卫星病灶,此时影像学表现多为浸润性病灶。随着肿瘤细胞的不断增殖最后融合为实体瘤,此时影像学则表现为实性占位性病变。原发性中枢神经系统淋巴瘤的嗜血管特性导致其极易侵犯血管壁,在早期沿血管周围间隙浸润性生长阶段,血管壁未被严重破坏,其增强效应可能不明显。晚期融合形成实体瘤后可能导致血管壁严重破坏,导致显著增强效应,甚至继发出血。虽然原发性中枢神经系统淋巴瘤具有嗜血管特性,但组织病理学显示通常无显著血管增生,其微血管密度低于高级别胶质瘤,因此原发性中枢神经系统淋巴瘤被认为是缺乏血供肿瘤^[19-20]。灌注成像(PWI)常呈低灌注表现,脑血管造影也显示缺乏血供特征^[21]。

原发性中枢神经系统淋巴瘤临床症状和影像学表现的个体和时间多样性增加临床诊断的难度,影响预后。在临床实践中,临床医师不仅要掌握其典型临床表现,更应注意其不典型临床表现,尽早通过脑组织活检术明确诊断,以早期治疗。
